THE GROWTH-AT-RISK (GaR) FRAMEWORK: IMPLICATION FOR UKRAINE

Anastasiya Ivanova, Alona Shmygel, Ihor Lubchuck

The views of authors don't necessarily represent the views of the National Bank of Ukraine

Motivation and Research Question

Motivation:

The main objective of this research is to contribute to developing the procedure of measuring the systemic risk to improve the process of macroprudential policymaking of the National Bank of Ukraine by applying and adapting the Growth-at-risk (GaR) framework to examine the macro-financial vulnerabilities, financial conditions, and other factors linked to the probability distribution of GDP growth in Ukraine.

Research question:

- Estimate the scope and consequences of large-scale downturns of GDP, under a given probability and time horizon, and to define factors that generated them.
- Explore the relationships between macrofinancial environment (financial conditions, credit and sectors' activity, and external conditions) and economic activity on different stages of Ukrainian economy.
- Examine the behavior of GDP growth distributions under different scenarios of economic development, as well as the historical ones, that have previously realized.

Motivation and Research Question

Policy implications:

- Enhances the existing methodology of assessing systemic risks and develop the procedure of measuring the systemic risk to improve the process of macroprudential policymaking;
- With the help of Growth-at-Risk measure, the NBU experts can assess the possibility and magnitude of adverse scenarios for the national economy, thus getting a proactive tool.
- With the help of derived future distribution of GDP growth, the NBU policymakers may enrich their forecasting tool that now is based on point-estimation to the scale of whole distribution.
- Helps to quantify the tradeoff between the tighter macroprudential conditions and, respectively, slower credit growth and financial stability.
- Helps to assess the applicability and relative usefulness of stress-testing baseline and adverse scenarios, thus contributing to fairer outcomes.
- With the help of GaR tool, it becomes simpler to communicate with the public on the risks to financial stability and the forecast of economic growth.

Methodology and Model (steps)

- I. Constructing indices which will represent three main explanatory variables of future GDP growth. These factors are:
 - Financial conditions index
 - Credit and Sectors Activity index
 - External conditions index
- II. Estimating quantiles regressions to identify the relationships between partitions and GDP growth.
- III. After estimating the pool of the quantile models, deriving GDP growth distribution via fitting a parametric form of a skewed t-distribution.
- IV. Based on the derived distribution of future GDP growth, conducting scenario analysis.

Methodology and Model (Model Specifications)

$$Q_{\tau}(Y_{t+q}) = \beta_0(\tau) + \beta_1(\tau)X_{t1} + \beta_2(\tau)X_{t2} + \beta_3(\tau)X_{t3} + Q_{\tau}(Y_t) + \varepsilon(\tau)_{t+q}, \text{ where}$$

$Q_{\tau}(Y_{t+q})$ – GDP growth q period ahead (the quarter) at a particular percentile,

τ – percentile,

t- time,

q- quarter,

X_{t1}, X_{t2}, X_{t3} – financial conditions index, credit and sectors` activity, External conditions index,

$\beta_0, \beta_1, \beta_2, \beta_3$ – sets of parameters associated with the τ th percentile,

$Q_{\tau}(Y_t)$ – GDP growth at the current period at a particular percentile (autoregressive term),

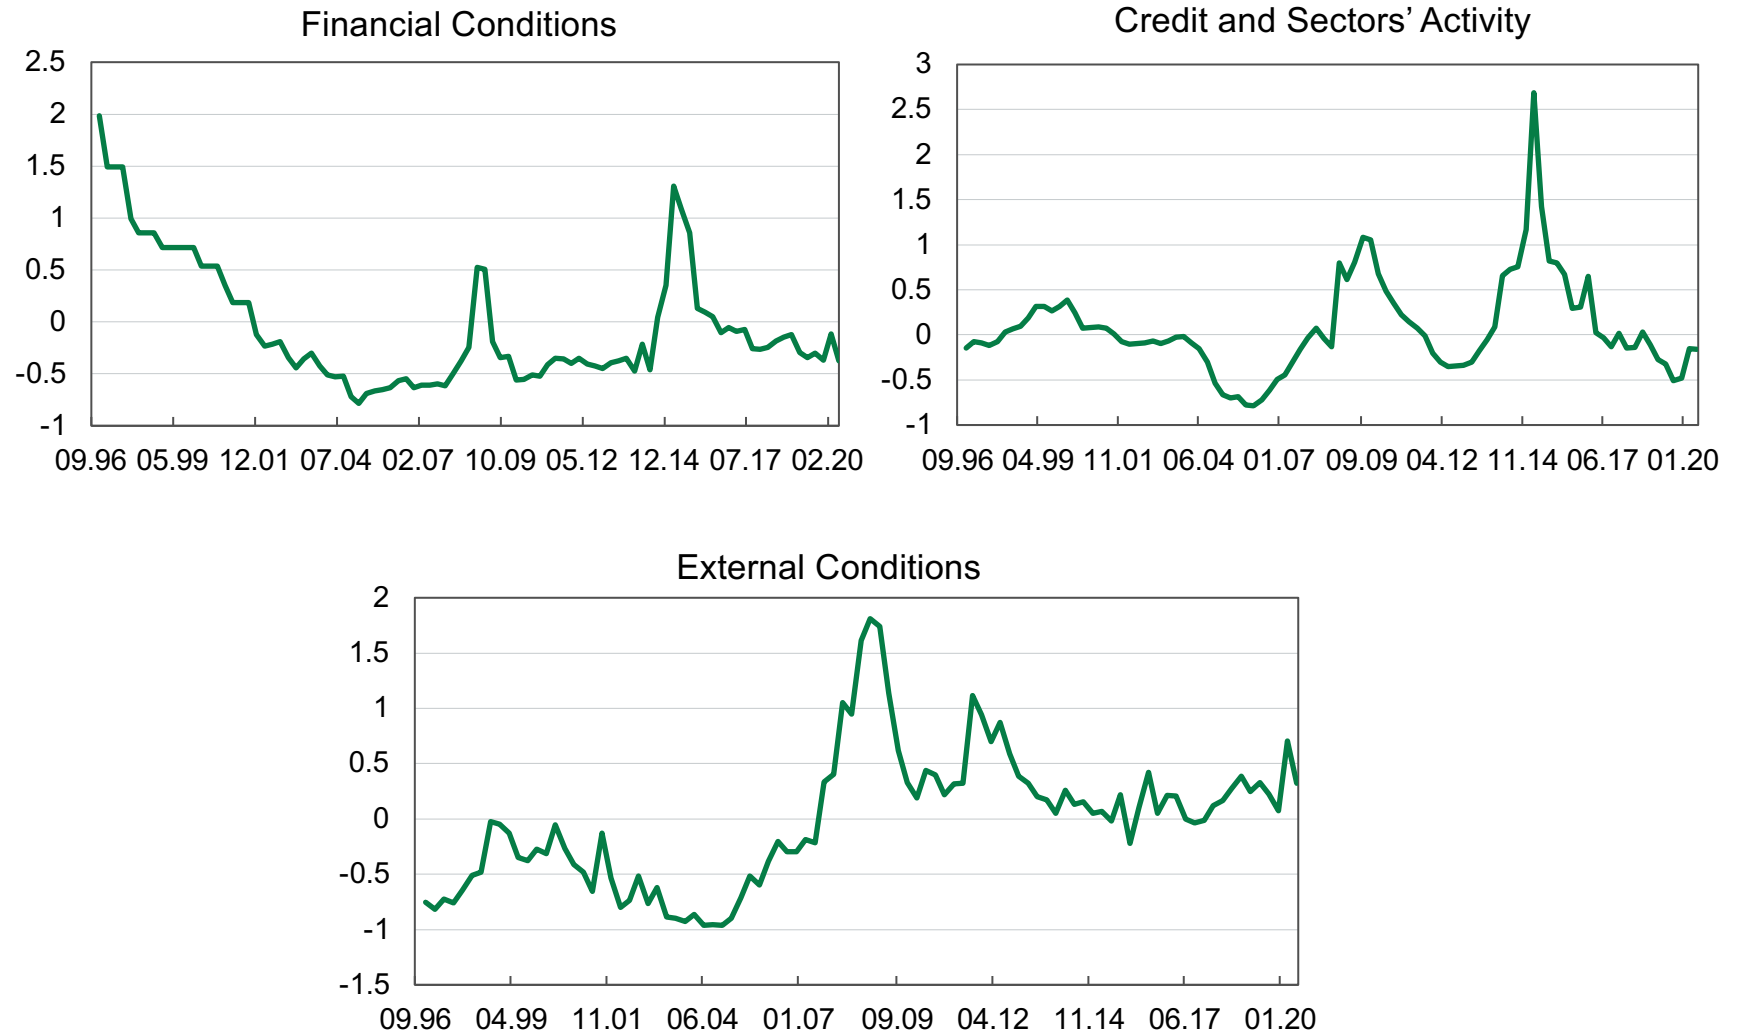

$\varepsilon(\tau)_{t+q}$ – residuals.

Step 1: Constructing indices. Variables

- We employed two approaches for constructing indices for the variables.
 - Aggregating variables inside each index with simple cross sectional average.
 - Conducting Principal Component Analysis which enables us to identify the relative importance of each indicator among one group of factors.
- We included the following indicators in the indices:

Financial Conditions	Credit and Sectors Activity		External Conditions	
Bond yields		Credit to GDP Gap		Credit dollarization
Corporate IR spread	Household	House price growth on a primary market, quarterly	Dollarization	Deposit dollarization
Household IR spread		House price growth on a secondary market, quarterly		FCI US
Corporate lending IR		PTR		CISS
HH lending IR		PTI		CA Deficit
RWA to Capital		HH debt to GDP		Commodity Prices (Index)
Corporate Eurobonds	Corporate	Corporate debt to GDP		GEPU Index
	Government	Public debt to GDP		
	Banking	Banks` leverage		
		Banks` ROA		
		Banks` ROE		

Step 1: Constructing indices. Cross-Sectional Average

Step 1: Constructing indices. PCA. Financial Conditions. Short

Financial conditions partition (index)

Relative contribution of the indicators

Note: The figure show indices dynamics for a shorter period than previous graphs due to data availability.

Step 1: Constructing indices. Credit and Sector` Activity

Credit and Sectors` Activity (index)

Relative contribution of the indicators

Step 1: Constructing indices. External conditions

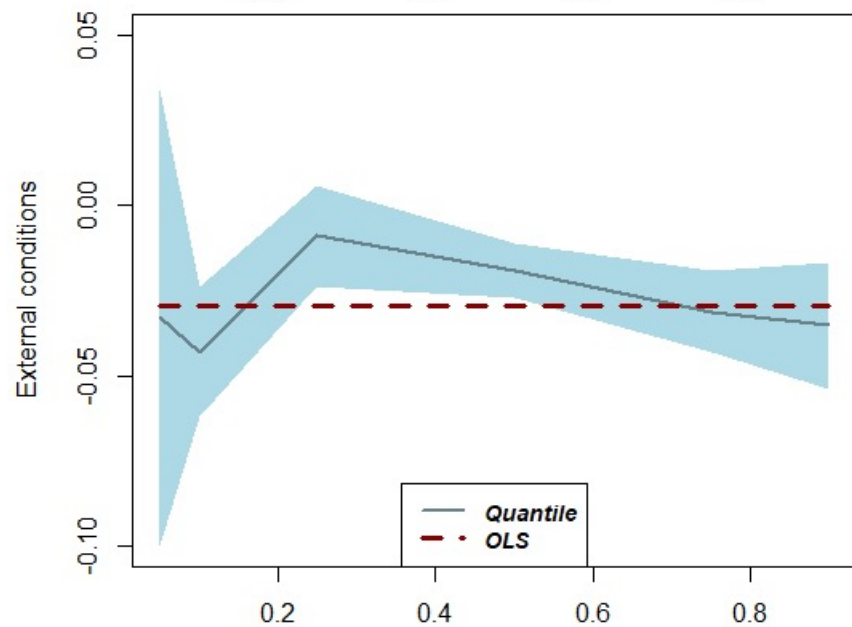

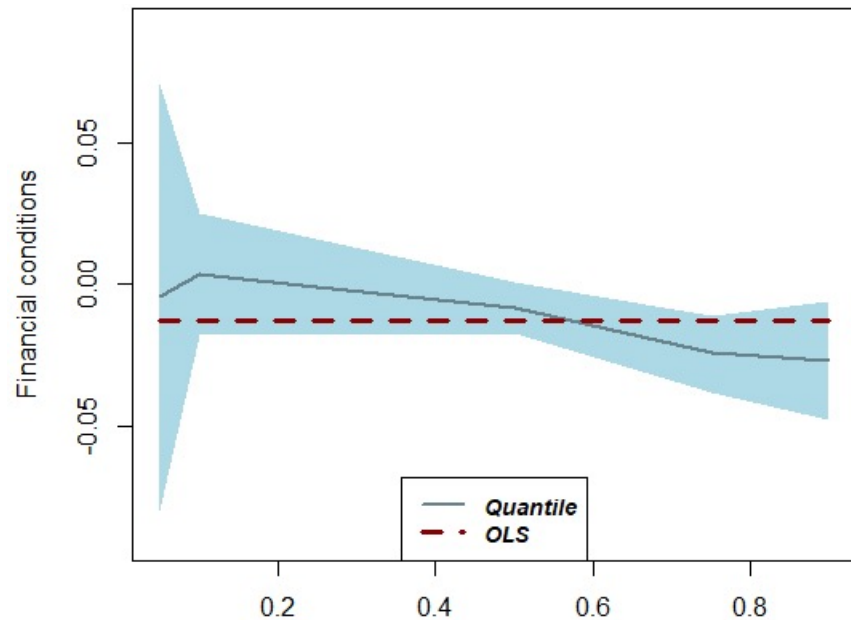

External conditions, index

Conclusions

- We applied and adapted GaR framework for Ukraine and explored the association between macrofinancial environment (financial conditions, credit and sectors` activity, and external conditions) and economic activity on different stages of Ukrainian economy.
- The model under PCA outperformed the model under CSA in terms of significance and stability of the coefficients and the predicting power. The results of the PCA model imply the negative relationship between financial conditions and future economic growth. Moreover, the impact of financial conditions is more than twice stronger in terms of magnitude on the lower quantiles.
- According to the fitted conditional GDP growth distribution 1q ahead, there is 5% probability that GDP will fall by at least 11.8% next quarter.

Further work

- Regression results differed depending on the approach of constructing index.
- Combining two model specifications for deriving the GDP growth distribution.
